Abstract. The article deals with electric heating systems applied in flowlines for providing their continued operation in wintertime. The problem of obtaining a given distribution of heat output along the length of the pipeline with electric heating system has been solved. It allows to maintain the same temperature sections being in different environments. As the object of investigation a polymer tube with an integrated electrical heating is chosen.

Keywords – flowline, electric heating, plastic pipe, hose-cord, equivalent circuit, four-pole.

I INTRODUCTION
To transport natural gas or oil from production areas to places to complex preparation and then to the points of connection to the main pipeline flowlines are used [1]. To prevent freezing product (oil and/or gas mixtures) being transported during a cold season the pipelines need heating. The most widely used heating occurs with electric power [2].

Electric pipeline heating system (EPHS) doesn’t undergo corrosion, stable to defrosting and can be powered by a common power supply system. Depending on the length of a pipe there are different EPHS (see Table 1). [3]

II MATERIALS AND METHODS
The complex design of steel and plastic pipes has been developed: some pipes have a system of distributed heating, the other include thermal insulation layer, and the third group are provided with reinforcing elements (relevant for polymer pipes) [5, 6, 7, 8, 9].

III RESULTS AND DISCUSSION
We have developed a new construction of polymer pipeline, which combines the advantages of hose-cord (multilayer polymer tube with electrical and other conductors) and the original EPHS. The development objective was to obtain the given thermal distribution along the length of the pipeline.

Pipeline with EPHS is hose-cord (Fig. 1.), consisting of an inner working tube 1 (flexible polymer tube, for example of low pressure polyethylene HDPE), on the top of which there is a reinforcing layer 2. It consists of a steel belt 3 and a layer of the armoring steel wire 4. The reinforcing layer 2 is covered with an intermediate layer 5, which is surrounded by a high-temperature thermal insulation layer 6 (e.g., glass fiber), which also serves as additional reinforcement. Around the high-temperature thermal insulation layer 6 EPHS is laid 7, which is distributed over the entire length of the pipeline. EPHS 7 is made of high resistance conductor 8 (e.g., steel, nichrome, etc.), winded with a step h around the working tube 1 and nonintersecting isolated low-resistance conductors 9 and 10 (e.g., copper) with a step H, wherein H »h.
different distances $L_i$. EPHS 7 is surrounded by a high temperature insulation layer 12 placed insulating layer 13 (for example, polyethylene foam). On which outer surface the polymeric waterproofing shell 14 (e.g., HDPE) [10].

By applying an electrical voltage to the low-resistance end of the isolated conductors 9 and 10 on EPHS 7 an electric current starts to flow and conductors 8, 9 and 10 are warm up. The electrical equivalent circuit of the EPHS is shown in Fig. 2.

EPHS parameter calculation is performed by applying the theory of quadrupoles. In this case, the EPHS is given in the form of a chain system (Figure 3), consisting of series-connected sections with discrete longitudinal resistances $R_k$ (low resistance conductor) and the transverse conductivity $G_k$ (high-resistance wire), where $k = 1,2 \ldots, n$ is a section number. The calculation consists in determining the parameters for each subsequent section using the parameters of the previous section by the transition matrix. [11]

**IV CONCLUSIONS**

The pipeline with EPHS is a complex technical solution to build a reliable system of transportation of petroleum products, ensuring trouble-free pumping of crude oil through the territory of the deposit. EPHS allows to get the required distribution of thermal power along the pipeline, which increases the reliability and provides energy saving when employing flowlines.
